2/25/12

1: Task 2.2

Claim: For all $l1: \alpha \text{ list}$ and all $l2: \alpha \text{ list list}$,

$$\text{ap}(l1, \text{concatap } l2) \cong \text{concatap}(l1 :: l2)$$

Proof:

$$\begin{aligned} & \text{concatap}(l1::l2) \\ \cong & \text{case } l1::l2 \text{ of } [] \Rightarrow [] \mid x::xs \Rightarrow \text{ap}(x, \text{concatap}(xs)) \quad \text{step} \end{aligned}$$

At this point, $l1::l2$ can be either be `nil` or `x::xs`. We will show both cases.

Case `nil`:

(both $l1$ and $l2$ are `nil`) since $[]::[] = []$:

$$\begin{aligned} & \text{case } [] \text{ of } [] \Rightarrow [] \mid x::xs \Rightarrow \text{ap}(x, \text{concatap}(xs)) \quad \text{def of concatap} \\ \cong & [] \quad \text{step} \\ \cong & l2 \quad \text{value of } l2 \\ \cong & \text{case } [] \text{ of } [] \Rightarrow l2 \mid \dots \quad \text{rev. step from ap} \\ \cong & \text{ap}([], []) \quad \text{rev. step, def of ap} \\ \cong & \text{ap}([], \text{case } [] \text{ of } [] \Rightarrow []) \quad \text{rev. step, def of concatap} \\ \cong & \text{ap}([], \text{concatap}([])) \quad \text{rev. step from concatap} \\ \cong & \text{ap}(l1, \text{concatap}(l2)) \quad \text{values of } l1, l2 \end{aligned}$$

Case `x::xs`:

$$\begin{aligned} & \cong \text{case } l1::l2 \text{ of } [] \Rightarrow [] \mid x::xs \Rightarrow \text{ap}(x, \text{concatap}(xs)) \quad \text{def of concatap} \\ & \cong \text{ap}(l1, \text{concatap}(l2)) \quad \text{reverse step} \end{aligned}$$

In both cases, the lemma holds. QED.

2: Task 2.3

Claim: For all $l : \alpha \text{ list list}$,

$$\text{concat } l \cong \text{concatap } l$$

Proof: We proceed by structural induction on l

Case []: Want to show: $\text{concat } [] \cong \text{concatap } []$ Consider:

$$\begin{aligned} & \text{concat } [] && \text{step} \\ \cong & \text{case } [] \text{ of } [] \Rightarrow [] \dots && \text{step} \\ \cong & [] && \text{step} \\ \cong & \text{case } [] \text{ of } [] \Rightarrow [] \dots && \text{reverse step} \\ \cong & \text{concatap } [] && \text{reverse step} \end{aligned}$$

Case $x::xs$: Inductive Hypothesis: $\text{concat } xs \cong \text{concatap } xs$ Inductive Step:

Consider:

$$\begin{aligned} & \text{concat } x::xs \\ \cong & \text{case } x::xs \text{ of } \dots \mid x::xs \Rightarrow \dots && \text{step} \\ \cong & \text{case } x \text{ of } [] \Rightarrow \text{concat } xs \mid y::ys \Rightarrow y::\text{concat } (ys::xs) && \text{step} \end{aligned}$$

In the list of lists xs , the first element can be the empty list, or a non-empty list. We will consider both cases. Case $x = []$:

$$\begin{aligned} & \cong \text{case } [] \text{ of } [] \Rightarrow \text{concat } xs \mid y::ys \Rightarrow y::\text{concat } (ys::xs) && \text{cont. from above} \\ & \cong \text{concat } xs && \text{step} \\ & \cong \text{concatap } xs && \text{IH} \\ & \cong \text{ap}([], \text{concatap } xs) && \text{Lemma 2} \\ & \cong \text{case } []::xs \text{ of } \dots \mid x::xs \Rightarrow \text{ap}(x, \text{concatap } xs) && \text{rev. step} \\ & \cong \text{concatap } []::xs && \text{rev. step} \end{aligned}$$

Case $x = y::ys$:

$$\begin{aligned} & \cong \text{case } y::ys \text{ of } [] \Rightarrow \text{concat } xs \mid y::ys \Rightarrow y::\text{concat } (ys::xs) && \text{cont. from above} \\ & \cong y::\text{concat } (ys::xs) && \text{step} \\ & \cong y::(\text{case } ys::xs \text{ of } \dots \mid x::xs \Rightarrow \text{case } x \text{ of } \dots) && \text{step, evaluate the case} \\ & \cong y::(\text{case } ys \text{ of } [] \Rightarrow \text{concat } xs \mid z::zs \Rightarrow \dots) && \text{step} \end{aligned}$$

Here we run into another fork in the road. We said $x = y::ys$, but this function evaluates differently based on whether or not ys is nil. So we will consider both cases, since both are possible. Case x

$$\begin{aligned}
&= y :: [] \\
&\cong y :: (\text{case } [] \text{ of } [] \Rightarrow \text{concat } xs \mid z :: zs \Rightarrow \dots) && \text{cont. from above} \\
&\cong y :: (\text{concat } xs) && \text{step} \\
&\cong y :: (\text{concatap } xs) && \text{IH} \\
&\cong y :: (\text{ap}([], \text{concatap } xs)) && \text{Lemma 2} \\
&\cong \text{case } y :: [] \text{ of } [] \Rightarrow 12 \mid x :: xs \Rightarrow x :: (\text{ap}(xs, 12)) && \text{rev. step, from ap} \\
&\cong \text{ap}(y :: [], \text{concatap}(xs)) && \text{rev. step} \\
&\cong \text{ap}(x, \text{concatap}(xs)) && x = y :: [] \\
&\cong \text{case } x :: xs \text{ of } [] \Rightarrow [] \mid x :: xs \Rightarrow \text{ap}(x, \text{concatap}(xs)) && \text{rev. step (concatap)} \\
&\cong \text{concatap } (x :: xs) && \text{rev. step}
\end{aligned}$$

Here we see that the lemma holds for the subcase when $x = y :: []$.

Case $x = y :: ys$:

$$\begin{aligned}
&\cong y :: (\text{case } ys \text{ of } \dots \mid z :: zs \Rightarrow z :: (\text{concat} \dots)) && \text{cont. from above} \\
&\cong y :: (z :: (\text{concat}(zs :: ys))) && \text{step} \\
&\cong y :: (z :: (\text{concat}(zs :: ys))) && \text{step}
\end{aligned}$$

This decomposition by `concat` will happen until the tail of the list is `nil`. Since lists are assumed to be finite, the decomposition will inevitably terminate. When the tail becomes `nil`, Case $x = y :: []$ holds.

I can't figure out the rest of this proof. However, I tried starting at the bottom of the proof and working up. Here is what I came up with...

$$\begin{aligned}
&\cong y :: (z :: (\text{ap } (zs, \text{concat } xs))) && \text{cont. from above.} \\
&\cong y :: (z :: (\text{ap } (zs, \text{concatap } xs))) && \text{cont. from above.} \\
&\cong y :: (z :: (\text{concatap } zs :: xs)) && \text{cont. from above.} \\
&\cong y :: (\text{concatap } ys :: xs) && \text{rev. step} \\
&\cong y :: (\text{ap}(ys, \text{concat } xs)) && \text{rev. step} \\
&\cong y :: (\text{ap}(ys, \text{concatap } xs)) && \text{IH} \\
&\cong \text{case } y :: ys \text{ of } [] \Rightarrow 12 \mid x :: xs \Rightarrow x :: (\text{ap}(xs, 12)) && \text{rev. step, from ap} \\
&\cong \text{ap}(y :: ys, \text{concatap}(xs)) && \text{rev. step} \\
&\cong \text{ap}(x, \text{concatap}(xs)) && x = y :: [] \\
&\cong \text{case } x :: xs \text{ of } [] \Rightarrow [] \mid x :: xs \Rightarrow \text{ap}(x, \text{concatap}(xs)) && \text{rev. step (concatap)} \\
&\cong \text{concatap } (x :: xs) && \text{rev. step}
\end{aligned}$$

I was almost there :(Partial credit please?

3: Task 2.4

1. lemma 3
2. lemma 3
3. since g and f are valuable, gof is valuable
4. since g and f are total, gof are total
5. lemma 3
6. step
7. step
8. $\text{map } g(\text{map } f []) \cong \text{map}(\text{gof}) []$
9. step
10. step
11. step, def of map
12. $\text{map } g(\text{map } f \text{ xs}) \cong \text{map } \text{gof } \text{xs}$
13. $\text{map } g(\text{map } f \text{ xLLxs}) \cong \text{map } (\text{gof}) (x::\text{xs})$
14. step
15. def of function composition
16. def of function composition
17. $***$, transitivity, and totality of map
